Sequence models & Attention mechanism

TOTAL POINTS 10

1.Question 1

Consider using this encoder-decoder model for machine translation.

This model is a “conditional language model” in the sense that the encoder portion (shown in green) is modeling the probability of the input sentence x .

☐ True

☒ False

1 point

2.Question 2

In beam search, if you increase the beam width B , which of the following would you expect to be true? Check all that apply.

☒ Beam search will run more slowly.

☒ Beam search will use up more memory.

☒ Beam search will generally find better solutions (i.e. do a better job maximizing $P(y | x)$)

☐ Beam search will converge after fewer steps.

1 point

3.Question 3

In machine translation, if we carry out beam search without using sentence normalization, the algorithm will tend to output overly short translations.

☒ True

☐ False

1 point

4.Question 4

Suppose you are building a speech recognition system, which uses an RNN model to map from audio clip x to a text transcript y . Your algorithm uses beam search to try to find the value of y that maximizes $P(y | x)$

On a dev set example, given an input audio clip, your algorithm outputs the transcript \hat{y} = "I'm building an A Eye system in Silly con Valley.", whereas a human gives a much superior transcript y^* = "I'm building an AI system in Silicon Valley."

According to your model,

$$P(\hat{y} | x) = 1.09 * 10^{-7}$$

$$P(y^* | x) = 7.21 * 10^{-8}$$

Would you expect increasing the beam width B to help correct this example?

☒ No, because $P(y^* | x) \leq P(\hat{y} | x)$ indicates the error should be attributed to the RNN rather than to the search algorithm.

☐ No, because $P(y^* | x) \leq P(\hat{y} | x)$ indicates the error should be attributed to the search algorithm rather than to the RNN.

☐ Yes, because $P(y^* | x) \leq P(\hat{y} | x)$ indicates the error should be attributed to the RNN rather than to the search algorithm.

☐ Yes, because $P(y^* | x) \leq P(\hat{y} | x)$ indicates the error should be attributed to the search algorithm rather than to the RNN.

1 point

5.Question 5

Continuing the example from Q4, suppose you work on your algorithm for a few more weeks, and now find that for the vast majority of examples on which your algorithm makes a mistake, $P(y^* | x) > P(\hat{y} | x)$ this suggest you should focus your attention on improving the search algorithm.

☒ True.

☐ False.

1 point

6.Question 6

Consider the attention model for machine translation.

☒ $\sum_t \alpha^{<t,t'>} = 1$ (Note the summation is over t' .)
1 point

7.Question 7

The network learns where to “pay attention” by learning the values $e^{<t,t'>}$, which are computed using a small neural network:

We can't replace $s^{<t-1>}$ with $s^{<t>}$ as an input to this neural network. This is because $s^{<t>}$ depends on $\alpha^{<t,t'>}$ which in turn depends on $e^{<t,t'>}$; so at the time we need to evaluate this network, we haven't computed $s^{<t>}$ yet.

☒ True

☐ False

1 point

8.Question 8

Compared to the encoder-decoder model shown in Question 1 of this quiz (which does not use an attention mechanism), we expect the attention model to have the greatest advantage when:

☒ The input sequence length T_x is large.

☐ The input sequence length T_x is small.

1 point

9.Question 9

Under the CTC model, identical repeated characters not separated by the “blank” character () are collapsed. Under the CTC model, what does the following string collapse to?

__c__o__o__k__k__b__o__o__o__o__o__o__o__o__k__k__k

☐ cokbok

☒ cookbook

☐ cook book

☐ coookkbooooooooookkk

1 point

10.Question 10

In trigger word detection, $x^{<t>}$ is:

☒ Features of the audio (such as spectrogram features) at time t .

☐ The t -th input word, represented as either a one-hot vector or a word embedding.

☐ Whether the trigger word is being said at time t .

☐ Whether someone has just finished saying the trigger word at time t .
